ABSTRACT

Although many casts have been made of the Carnegie Museum's iconic *Diplodocus*, initially in plaster and more recently in various plastics, one stands alone as having been cast in concrete. This skeleton, made from the original Carnegie molds starting in 1956–1957, was unveiled at the Utah Field House of Natural History in Vernal, Utah, in 1957, and stood outside the museum for three decades. The fate of the molds after this casting is uncertain. The concrete *Diplodocus* was the museum's icon for 32 years until the weather damage became too great. The cast was then taken down and repaired, and fresh molds made from it by Dinolab in Salt Lake City. From these molds, a new replica was cast in water-expanded polyester and mounted inside the Field House. This cast was moved to the Field House's new location in 2004 and was remounted in the atrium, but the old concrete cast could not be easily remounted and was instead transferred to the Prehistoric Museum at Price, Utah. It has, however, yet to be remounted there, as it awaits a new building for the museum. Meanwhile, the new molds have been used to create more *Diplodocus* casts that are mounted in Japan and elsewhere, and have also furnished missing parts of the iconic rearing *Barosaurus* skeleton in the atrium of the American Museum of Natural History in New York City. Thus, the concrete *Diplodocus* of Vernal has become one of the most influential of all *Diplodocus* specimens, second only to the Carnegie original.

INTRODUCTION

Diplodocus is a sauropod dinosaur from the Late Jurassic of North America, found in the extensive Morrison Formation of the western states. Although larger and more complete sauropods are now known, *Diplodocus* was the first giant dinosaur known from a substantially complete skeleton—the Carnegie Museum's iconic specimen CM 84 (figure 1). This individual, the holotype of the species *Diplodocus carnegii*, was discovered and excavated in early July 1899 at Sheep Creek in Albany County, Wyoming, by a team under the leadership of Jacob L. Wortman. As described by Taylor and others (in preparation a) and expounded in detail by Nieuwland (2019), casts of this important specimen were sent all around the globe, and as a result this individual became – and remains – the single best-known dinosaur in the world.

Among the numerous *Diplodocus* casts that have been mounted, many have been made in plaster, in-

Citation for this article.

Taylor, M.P., Sroka, S.D., and Carpenter, K., 2023, The concrete *Diplodocus* of Vernal—a cultural icon of Utah: *Geology of the Intermountain West*, v. 10, p. 65–91, <https://doi.org/10.31711/giw.v10.pp65-91>.

Figure 1. Mounted skeleton of *Diplodocus carnegii*: the original fossil material mounted in the public gallery of the Carnegie Museum in Pittsburgh, Pennsylvania. This mount consists primarily of the holotype specimen CM 84, augmented by elements from CM 94 and CM 307, plus casts and sculptures based on several other specimens. Skeleton in left anterolateral view, with *Homo sapiens* Mathew J. Wedel for scale. Photograph by Michael P. Taylor.

cluding all the oldest ones; and many have been made in modern lightweight materials such as water-expanded polyester (WEP). However, one stands alone, having been cast in concrete by the Utah Field House of Natural History State Park Museum in Vernal, Utah.

In this paper, we will briefly summarize the history of the original Carnegie *Diplodocus*, discuss how the concrete cast came to be, and consider its legacy.

NOMENCLATURE

A distinction is made between molds and casts. A mold is a negative structure made from an origi-

nal specimen (or, less commonly, a cast), in which the spaces inside the mold match the shapes of the original specimen. A cast is a positive structure, a copy made of a specimen made by filling a mold, and its shape matches that of the original specimen.

HISTORY OF THE CONCRETE *DIPLODOCUS*

The Original Carnegie *Diplodocus*

As related by Taylor and others (in preparation a), the industrialist and philanthropist Andrew Carnegie was inspired by a newspaper article in the late 1800s to ask the director of the museum that bears his name to obtain a giant dinosaur skeleton for exhibit. In July 1899, an expedition from the museum found a largely complete specimen of the sauropod *Diplodocus*, which when excavated and prepared was given the specimen number CM 84 and described in John Bell Hatcher's (1901) monograph as the new species *Diplodocus carnegii*. In 1907, this specimen was mounted in the new dinosaur hall of the Carnegie Museum, its missing portions filled in with bones from a second *Diplodocus carnegii* specimen CM 94, and casts and sculptures based on other closely related specimens, some of them from other museums.

This mounted skeleton quickly became the icon of the Carnegie Museum, and has remained so up to the present, even after the addition to the dinosaur hall of the even larger apatosaurine mounted skeleton CM 3018, which was designated the holotype of the new species *Apatosaurus louisae* (Holland, 1915; Gilmore, 1936). The *Diplodocus* skeleton, known by the rather inelegant nickname "Dippy," has been moved and modified several times in the years since its initial mounting, most recently in a major redesign of the Carnegie Museum in 2005–2007. It presently co-stars with CM 3018 in the new Jurassic Hall.

The First Casts of the Carnegie *Diplodocus*

Well before the mounting of the real bones of CM 84, King Edward VII of England asked Carnegie for a

Diplodocus skeleton to be displayed in the British Museum (Natural History) in London. Carnegie naively hoped to put an end to war by encouraging arbitration instead (Nieuwland, 2019, p. 55), and to this end was always keen to gain influence with heads of state. He therefore enthusiastically agreed to the King's request and instructed museum director William J. Holland to find another specimen. Considering it unlikely that another *Diplodocus* of the same quality would quickly become available without great expense, Holland proposed instead to create a replica. Carnegie swiftly agreed.

Holland's chief fossil preparator Arthur Coggeshall oversaw the creation of a set of plaster molds by a crew of Italian plasterers led by Serafino Agostini. The molds corresponded to the bones of CM 84 and the other bones that were to be included in the real-bone mount a few years later. Some differences exist between the molds and the real skeleton (for details, see Taylor and others, in preparation a) but the molds corresponded closely to the original skeleton. These molds were used to create not just the cast skeleton requested by King Edward VII, but four additional casts. After the British Museum unveiled its mounted cast to great fanfare on May 12, 1905, and after the original bones were mounted at the Carnegie Museum in 1907, Carnegie went on to gift the other four casts to Kaiser Wilhelm II of Germany, Président Armand Fallières of France, Emperor Franz Joseph of Austria and King Victor Emmanuel III of Italy, in 1908 and 1909. As with the London replica, Holland and his chief preparator Arthur S. Coggeshall travelled to each recipient country to supervise the mounting of the casts.

Buoyed by the success of his donation program, Carnegie authorized the creation of five more casts from the same molds, destined to be donated to other heads of state. Between 1910 and 1913, three of these were given to Tsar Nicholas II of Russia, President Roque Sáenz Peña Lahitte of Argentina, and King Alfonso XIII of Spain. But the outbreak of the Great War in 1914 (World War I) put an end to Carnegie's dream of arbitration replacing warfare. When he died in 1919, not only had the two remaining skeletons not been donated, but the museum was left relatively impoverished. The continuing funding from Carnegie's trust "certainly did not allow

the natural history museum to keep up its competition with New York's AMNH" (Nieuwland, 2019, p. 250). As noted by Gangewere (2011, p. 24), Carnegie's gifts to his Institute and Library during the last 20 years of his life amounted to \$11,729,470 (about \$200,000,000 in current dollars); but in the 20 years after his death, only an additional \$1.4 million (in the dollars of the time) was provided – and relatively little of this would have gone to the Natural History Museum. While Holland had considered closing the Carnegie Quarry, near Vernal, as early as 1917 (Carpenter, 2018, p. 13), the reduction in funding must have played some part in the eventual decision to abandon it in 1922. Only years later, with the aid of funds from Carnegie's widow Louise, would the last two casts be sent to Mexico City (in 1930) and Munich (in 1934), the latter never even being mounted.

The molds, having last been used in the 1910s, then lay forgotten in the basement of the Carnegie Museum for more than 40 years (Untermann, 1959, p. 364).

The Utah Field House Museum in Vernal

As Harvey (1991) and Carpenter (2018) explain in detail, the Carnegie Quarry in northeastern Utah (now in Dinosaur National Monument) was exploited extensively in the early 20th century by teams from the Carnegie Museum led by Earl Douglass. Although Douglass himself was on good terms with Utah paleontologists, all the dinosaur material excavated at this quarry was of course shipped to the Carnegie in Pittsburgh, Pennsylvania, leading to growing resentment among Utahns that their own state was not benefitting from the discoveries being made there. The inhabitants of Vernal, only 20 miles from the quarry, were frequent visitors and supplied Douglass's crew. Two of these local crew members would go on to work at museums: Golden York at the University of Utah, and LeRoy "Pop" Kay at the Carnegie Museum. Commercial groups at Vernal hoped that a visitor center at the quarry would provide some revenue for the state and the town, but William Holland, the director of the Carnegie Museum, treated these plans with contempt, exacerbating existing tensions between the western state and the eastern museum.

As recounted by Untermann and Untermann

(1971), the genesis of the Utah Field House lay with Arthur G. Nord, supervisor of the Ashley National Forest. In the 1930s, he and others became concerned that the fossil wealth of the Vernal area was being stripped by museums outside the locality. Realizing the importance of tourism to Utah, Nord recommended that a museum could position Vernal as a gateway to the state on U.S. Highway 40 (Kirby, 1998, p. 2). The creation of a museum in Vernal was formally proposed by Dr. J.E. Broadus of the State Museum Association at the Vernal Lions Club meeting of September 9, 1934 (Anonymous, 1969), and it was reported in the local press only 18 days later (Anonymous, 1934). However, the idea languished for nine years until the Club returned to it on September 6, 1943 (Anonymous, 1969). A museum committee was then formed to advocate for a local museum (Anonymous, 1943). A state senate bill approving the museum was passed in 1945, and the next year Governor Herbert B. Maw made \$200,000 available to construct the museum building (Anonymous, 1969). G. Ernest Untermann was appointed director of the museum project, and his wife Billie, a capable scientist and administrator who became the first female naturalist at Dinosaur National Monument (Kirby, 1998, p. 2), was the Staff Scientist. Based on drawings created by the Untermanns, Salt Lake City architect Miles E. Miller drew up the plans, and the building was erected by Dorland Construction Company. The work was begun on October 16, 1947, and completed on July 1, 1948, and the building was dedicated on October 29, 1948, by Governor Maw.

The Concrete Cast in Vernal

As noted above, Vernal native J. LeRoy Kay had gained his entry to paleontology by working with Earl Douglass at what was then the Carnegie Quarry. After excavation there ended, Douglass had recommended that the Carnegie Museum hire Kay to continue work on removing the collected dinosaur bones from their encasing rock, writing to museum director Douglas Stewart on September 20, 1922 as follows:

"I understand that you are contemplating giving Mr. J. LeRoy Kay the opportunity to gain a wider experience by allowing him the opportunity of going to Pittsburg [sic] where he can for a time have the

advantages of the laboratory, museum, and library. While I would not advise any man to take up museum work if he has a family to support an[d] is not wealthy, Mr Kay is a very capable and resourceful man and can later turn his hand to more remunerative work if he wishes. If the museum is to continue the work of collecting especially in this field it will undoubtedly be the gainer by giving him this opportunity.”

Working at the Carnegie Museum for the next 30 years, Kay rose to become the head of the museum’s Section of Fossil Vertebrates. He was in this post when, in 1952, museum director Graham Netting started thinking about purging the collections of dinosaur material (Rodeck, 1952; Tschopp and others, 2019, p. 10) because the dinosaur bones took up too much storage space (Lee, 1955a, 1955b). Kay would later announce to the vertebrate paleontology community that the specimens had been “unfrozen” (Wright, 1956, p. 26).

The initial downsizing plan was soon scaled back to removing only the duplicate specimens. Among the materials to be disposed of were the plaster molds that had been used for the *D. carnegii* casts. The molds were large and heavy, and some were damaged and coated with coal dust from the coal-fired heating system. Kay, who was close to retirement and planned to move back to Vernal, wanted to find a home for the molds in his own state. He first contacted the Utah State Museum (now the Natural History Museum of Utah in Salt Lake City), but the museum was not willing to pay for the molds to be shipped. Ernest Untermann had been trying to obtain a dinosaur skeleton for the Utah Field House and stepped in at this point.

In 1952 (not 1955 as stated by Untermann and Untermann, 1971), Kay gifted the original plaster molds of the Carnegie *Diplodocus* to the Field House (Untermann, 1952, 1959), on the condition that the Field House would arrange transportation. As the molds weighed 5 tons (Untermann, 1956) this was no small undertaking. Local trucker Grant Southam used his own equipment to transport the molds at cost, and the Utah Lions Club provided the necessary \$1000 payment. The molds arrived on or shortly before August 7 (Untermann, 1952) (figure 2). However, having al-

Figure 2. The original *Diplodocus* molds created by the Carnegie Museum, shown in the Utah Field House some time between 1953 and 1955. In the background to the left is the mold for the sacrum and coalesced ilia, seen in right ventrolateral view with anterior to the top. The molds closely follow the shapes of the bones they were modelled from, but are noticeably bulkier. Scanned by Eileen Carr for the J. Willard Marriott Digital Library, image ID 1212242. Used by permission, Uintah County Library Regional History Center.

ready been used to create ten casts, they were by this time “deteriorating” (Gangewere, 1999, p. 17), “almost unusable” (Nieuwland, 2019, p. 251), and “in pretty bad shape” (Ken Carpenter, University of Colorado Museum, written communication, 2022).

Curiously, the poor condition of the molds is not discussed in Untermann’s (1959) otherwise comprehensive account of the creation of the Vernal cast. He recounts that the molds were dirty with Pittsburgh soot, requiring a steam bath, and that some repairs were necessary for molds that were actually broken, but the erosion and decay arising from ten prior castings are not mentioned.

Since the mounted skeleton’s 76-foot length would be too long for the museum’s 50-foot-long exhibit halls, plans were made to situate it outside the museum. Wind, rain, and extreme temperatures (the Vernal climate typically ranges between -10°F and 89°F , and extremes of -40°F and 100°F have been recorded) required a more robust casting material than the usual plaster. After some experimentation with different materials, the team set-

tled on a mix of one part cement to three parts Aggralite (a lightweight aggregate made of volcanic pumice). The complete cast would consist of about 600 pieces, many more than the number of bones, as the complex vertebrae were made from eight or more pieces (Anonymous, undated). About a hundred of these pieces had been completed when Otto Buehner, president of Salt Lake City's Otto Buehner Concrete Products Company, visited the museum, became interested in the casting, and expressed doubts about the use of Aggralite (Untermann, 1959, p. 365). Further experimentation, aided by Buehner's experienced workers, resulted in the selection of a new mixture, one part cement to three parts aragonite (the high-pressure polymorph of calcium carbonate). Most of the pieces were cast in this material by Grant Merrell, the museum's preparator, at the Otto Buehner facilities, with the more intricate parts completed at the museum. Reinforcing wire and rods were used where necessary, and the completed bones were coated in fiberglass to protect them from the elements. The Buehner Company benefitted from its involvement with the casting, as they discovered in the course of the process that fiberglass, when set with a catalyst, made a better and cheaper adhesive than they had previously been using to repair Italian marble when it was broken in transit. The Field House also adopted fiberglass as its bonding agent of choice after positive experiences with the concrete cast.

The result of all this work was nearly 600 concrete elements, which then had to be put together into a skeleton. First, the individual bones were assembled from their pieces, work done by the Untermans and Merrell. Identifying numbers on the molds had mostly faded with age, so this had to be done from anatomical principles. Pieces were fastened together with steel rods and bonded by fiberglass. The assembled bones were then laid out in the workshop to verify that everything was present and correct (figure 3; Untermann, 1959, figures 1 and 2).

With this done, the work moved outside. On a concrete base, and surrounded by a chain-link fence, the latter provided by the same Vernal Lions Club that had paid for the molds to be transported, the cast bones were assembled: sacrum and pelvis first (figure 4A), then hind limbs, dorsal vertebrae, caudal and cervical ver-

tebrae, and skull (figure 4B), and then finally the front limbs and ribs. The skull was mounted 21 feet above the ground at the end of a somewhat elevated neck, in a posture that corresponds well with the prediction of Taylor and others (2009) that sauropods, like extant tetrapods, habitually held their necks elevated at the base. The whole skeleton was not only supported on a steel scaffolding, but also guyed by thinner rods, enabling it to withstand 70 mile per hour winds that uprooted nearby trees (Untermann, 1957, 1959, p. 367–368). The completed concrete skeleton weighed 8 tons (Untermann, 1957).

The outdoor cast was dedicated on June 8, 1957, during the Utah State Lions Club convention at Vernal (Anonymous, undated), in a ceremony attended by J. LeRoy Kay, Arthur G. Nord, and G. Ernest Untermann (Anonymous, 1957), not on June 6 as reported by Untermann and Untermann (1971). The work had taken about a year and a half, from early 1956, and cost only \$10,000 in total (about \$105,400 in 2022 dollars), almost all of it in salary. The cast stood for 32 years (figure 5). It was repainted on June 22, 1967 (figure 6), in what was likely a periodic event (Anonymous, 1967).

The Fate of the Original Molds

So far as we have been able to determine, the casting of the concrete *Diplodocus* of Vernal was probably the last time the Carnegie Museum's original molds were used to create a complete new cast. However, that was not Untermann's intention. As early as June 1956, well before the completion of the Vernal cast, he was in negotiation with Theodore Downs, Curator of Vertebrate Paleontology at the LACM, to have the molds shipped there when the Vernal mount had been erected (Untermann, 1956). Furthermore, tentative plans were already in place for the molds to subsequently be used by "some museum in the State of Louisiana" (Ogawa, 1957), most likely either McNeese State College (now McNeese State University) or Louisiana State University (Downs, 1957); Michigan State University had also expressed an interest (Downs, 1957).

Downs's intention was to mount the LACM cast indoors, underneath the recently added hanging skeleton of a 70-foot-long blue whale, in the Hall of Evolving Life

Figure 3. Field House Museum Director G. Ernest Untermann (left), and his wife, Staff Scientist Billie Untermann (right), grouting the cast dorsal vertebrae of the Field House's concrete *Diplodocus*. January 24, 1957. Scanned by Aric Hansen for the J. Willard Marriott Digital Library, image ID 1086940. Used by permission, Uintah County Library Regional History Center.

(Downs, 1956). By May of 1957, however, this project was foundering due to “lack of room in the [Los Angeles] Museum, lack of time and money for technological supervision, labor and material, and perhaps lack of interest also” (Ogawa, 1957). More specifically, LACM had recently acquired the California Institute of Technology collection of 55,000 vertebrate fossils, and needed the display space for the dozen or so exhibit specimens that were included (Downs, 1957). With the Los Angeles plan having fallen through, Untermann followed up with McNeese State College, but they failed even to reply to three letters (Untermann, 1958) and so were removed from consideration.

Untermann remained anxious to get rid of the molds, which were taking up far too much of the small museum's limited space. In his 1959 account, he wrote (p. 368–369):

“Several museums in the United States and from lands as distant as Japan and Italy have expressed a desire to acquire the molds and cast a *Diplodocus* of their own from either plaster or some of the newer synthetics. To date no museum has apparently been able to make satisfactory arrangement for the acquisition of the molds and the casting of a skeleton. We still have the molds in Vernal, and any muse-

Figure 4. Assembly of the outdoor concrete *Diplodocus* at the Utah Field House in 1957. (A) In right posterolateral view. The sacrum and fused ilia having been mounted on the main support to begin the process, the hind limbs, last four dorsal vertebrae and first caudal vertebra have now been added. (B) In left anterodorsolateral view, probably taken from the roof of the museum. The mount is almost complete, with only the forelimbs, their girdles and the dorsal ribs yet to be attached. Note that, contra Untermann (1959, p. 367–368), the skull is already in place. Both images scanned by Aric Hansen for the J. Willard Marriott Digital Library, image IDs 1090660 and 1090647. Used by permission, Uintah County Library Regional History Center.

um, anywhere, is welcome to them just for hauling them off. [...] The *Diplodocus* on the lawn of the Utah Field House is the eleventh replica to be cast from the molds [...] Does anyone wish to cast the twelfth?”

From here, though, the story becomes uncertain and

accounts are contradictory. Sassaman (1988) reported that “the molds finally fell apart because of old age soon after it [the concrete *Diplodocus*] was made.” Similarly, Ilja Nieuwland (written communication, 2022; Huygens Institute, Royal Netherlands Academy of Arts and Sciences) says that “The original moulds were thrown away somewhere during the 1960s (nobody at the [Carnegie Museum] could be more specific than that),” suggesting that the molds may have been returned to their origin.

Both these accounts seem to be in error, however. As shown by a 1960 report in the *Vernal Express* newspaper (Anonymous, 1960a; figure 7; see also Carr and Hansen, 2005), in the middle of July 1960, the molds were collected by the Rocky Mount Children’s Museum (now the Rocky Mount Imperial Center, Children’s Museum & Science Center) in North Carolina, with the intention that they would be used to create a twelfth cast, which would be mounted outside the museum building next to the Tar River in Rocky Mount’s Sunset Park. However, it seems the new cast was never completed. Reports in the Rocky Mount *Evening Telegram* from April to July 1960 (Anonymous, 1960b; Bell, 1960a, 1960b; Williams, 1960) enthusiastically announced and discussed the impending arrival, and the later articles say that by July 7, 1960, museum board president Harold Minges had left for Utah to collect the molds. In fact, Minges took his whole family on this trip to collect the molds (Leigh Minges in Herring, 2022a). Anonymous (1960a) confirmed that the molds were collected on or around July 14, 1960. However, as Rea (2001, p. 210) reported, “from Vernal the molds kept travelling – first, to the Rocky Mount Children’s Museum in Rocky Mount, North Carolina, although a cast was never made there.” Similarly, Moore (2014, p. 234–235) stated that “From Vernal, Utah, [CM] molds of *Diplodocus carnegii* are shipped to Rocky Mount Children’s Museum in Rocky Mount, North Carolina. Because of the age-related damage to the molds, a cast was never prepared.”

At first, there was some excitement in Rocky Mount. Mae Woods Bell, who had been the museum director ever since its creation in 1951 (Anonymous, 1962b) made presentations about the dinosaur project to the Rotary Club (Anonymous, 1960c) and the Lions Club (Anonymous, 1960d). On August 26, 1960, Bell report-

Figure 5. The completed outdoor *Diplodocus* mount in a rare color photograph (undated). Scanned by Eileen Carr for the J. Willard Marriott Digital Library, image ID 415530. Used by permission, Uintah County Library Regional History Center.

ed that casting “will start soon” (Anonymous, 1960d), but evidently that work was significantly delayed as nearly a year later on June 11, 1961, the museum reported that “work will begin here Monday on a replica of a pre-historic dinosaur that will eventually tower 21 feet in Sunset Park [...] the project will consume many months before the animal will be erected on a frame in the park” (Anonymous, 1961a). Already by this point the disorganization and physical state of molds was of concern as “Several months will be involved classifying and preparing molds for casting” (Anonymous, 1961a).

An invitation was now issued to local citizens who wished to volunteer for the work, and they began to work on Monday and Tuesday evenings (Anonymous, 1961a) in a warehouse provided by Minges (Anon-

ymous, 1962b) on Hill Street, east of the intersection with Washington Street behind the old Pepsi bottling plant (Alan Anderson in Herring [2022a]). The Tuesday sessions were soon halted due to the hot weather (Anonymous, 1961b). Their suspension may have been intended as a temporary measure but by September 28, “The dinosaur project [was] progressing steadily, with museum personnel, trustees and volunteers working each Monday night” (Anonymous, 1961c). On October 10, Bell told the Junior Woman’s Club that “the work of the dinosaur was progressing nicely” (Anonymous, 1961d), and on January 9, 1962, Harold Minges told the museum’s annual meeting that the dinosaur was “rapidly being brought back to life by museum members” (Anonymous, 1962a). From this we must conclude that

Figure 6. The outdoor *Diplodocus* mount is repainted on June 22, 1967, in what was likely an periodic event. Field House employee Ivan Hall applies a mixture of linseed oil and brown stain while G. Ernest Untermann holds the ladder. Scanned by Eileen Carr for the J. Willard Marriott Digital Library, image ID 1091738. Used by permission, Uintah County Library Regional History Center.

some elements had been successfully cast by this point. On February 20, 1962 the Rocky Mount *Evening Telegram* reported, presumably with Bell's authority, that "during the year prospects are bright for the Museum's 'big' project to be completed." This optimism was to prove misplaced, however: nearly two years later on January 8, 1964 new museum president Ted P. Williamson called for "completion of the dinosaur project [...] which they hope to have on display during the year"

(Anonymous, 1964a); on December 8 that year, Bell told trustees that "work is continuing on the dinosaur project" (Anonymous, 1964b). Still the work lingered on, and as of March 23, 1966, John Thompson and Harold Minges were listed as co-chairmen of the Museum's Dinosaur Committee (Anonymous, 1966). The last mention of the project in the *Telegram* is in response to a question from "E.E.A." published on March 3, 1968, "What happened to the giant concrete dinosaur project at Sunset Park?" (Anonymous, 1968). "There is no positive answer concerning the future of this project," runs the reply. Minges is quoted as saying "The project was delayed for several years for one reason or another. The molds now are stored in the old Avalon Airport building on NC 97 East. We expect to resume work on the project in the spring."

Avalon Airport was a small airstrip on Leggett Highway in the mid-1940s (at that time known as Route 95, later changed to Highway 97 to avoid confusion with the new Interstate 95.) It was closed after operations were moved to Rocky Mount Municipal Airport on North Church Street (Herring, 2022b), and all buildings associated with it are now gone; there is still a local airport on Highway 97, but it is a completely different complex on the west side (Traci Thompson, Braswell Memorial Library, written communication, 2022). It seems likely, but is not certain, that the molds and any elements that had been cast from them, were destroyed or discarded when the old building was demolished.

At any rate, by 1985 the molds seem to have been lost. The then curator of the Utah Field House wrote to the Rocky Mount Children's Museum to ask whether a cast had ever been made and mounted, and what had happened to the molds (Laraba, 1985). In his response, the Rocky Mount Museum director wrote that "we do not have the molds nor do I know where they went" (McKinnon, 1985). It seems then, that while some casts were probably made from the molds, the project petered out and the casts as well as the molds were lost or destroyed.

Hurricane Floyd devastated Rocky Mount in 1999, with flooding from the Tar River destroying the original Children's Museum along with all its exhibits and records (Leigh White, Rocky Mount Children's Museum, written communication, 2022), so no records survive

Figure 7. The original *Diplodocus* molds being loaded onto a truck for shipment to the Rocky Mount Children’s Museum, North Carolina, on or shortly before July 14, 1960. From left to right: truck driver William Randolph Turnage, Field House employee Dee Hall, and Field House director G. Ernest Untermann. Scanned by Aric Hansen for the J. Willard Marriott Digital Library, image ID 1086142. Used by permission, Uintah County Library Regional History Center.

that could confirm the eventual outcome, if any, of the *Diplodocus* project. The museum was located next door to a municipal water treatment facility that also flooded and released unknown chemicals, so museum property that might have otherwise been salvageable in that area was deemed contaminated and had to be destroyed. If any molds or casts were in storage at the Children’s Museum at this time, then this was likely the end of their story.

The Children’s Museum was re-established at the newly built Imperial Center, where it still resides, but no trace exists there of molds or casts of *Diplodocus*. Corroborating the likely conclusion that no cast was ever completed, most staff who worked at the museum in the 1980s at its old location do not recall any such cast (Leigh White, Rocky Mount Children’s Museum, written communication, 2022). Potentially contradicting this, however, Jan Engle Hicks, Curator of Education at the Rocky Mount Children’s Museum from 1971–2002, has a memory of *Diplodocus* casts being on exhibit at the museum when she started work in 1971. She does not recall if they were still part of the museum collection in 1999 when the collection was destroyed. It is possible that the *Diplodocus* specimens that Hicks remembers on display were not casts made from the Carnegie molds, but other specimens that were given to the Children’s Museum by LeRoy Kay from the Carne-

gie Museum (Bell, 1960a).

Whether or not a cast was made at Rocky Mount, it is possible that this was not the end for the molds. Williams (1960) had written that “the local museum plans to pass the molds on to the next group that makes satisfactory arrangements to acquire them [...] Already two inquiries have come to the Children’s Museum asking ‘Who has them next?’” Rea (2001, p. 210) claims that “Eventually the molds found their way to the Houston Museum of [Natural] Science, where they were used to fill in gaps in the *Diplodocus hayi* skeleton that had been swapped from Pittsburgh to Cleveland before ending up in Houston,” citing a personal communication from John S. McIntosh. (The skeleton in question is that of CM 662, which became CMNH 10670 in Cleveland, then HMNS 175 in Houston. Having been nominated as the holotype of the new species *Diplodocus hayi* by Holland [1924, p. 399], the species was later moved to its own new genus *Galeamopus* by Tschopp and others [2015, p. 267].) Due to the loss of the Rocky Mount Children’s Museum records, we cannot confirm that they ever shipped the molds to Houston; and the molds cannot be located at the Houston Museum (Robert Bakker, HMNS, written communication, 2022). Brian Curtice (Fossil Crates, written communication, 2022) also reports that he was in Houston in 1995 and did not see the molds in the collection, nor hear of their ever

having been there. In the absence of evidence that the molds ever made it to Houston, it seems more likely that the missing bones in HMNS 175 were cast and supplied by Dinolab Inc., using the second-generation molds described below, and that Rea (2001) misreported this.

As recently as 1988, Rolfe (1988) wrote to LuRae Caldwell of the Utah Field House, on behalf of the Royal Museum of Scotland, “At present I am exploring the possibility of re-using the Carnegie Museum, Pittsburgh moulds, although there is considerable doubt about whether they are up to the job, after so much previous use.” Sadly, his letter does not mention their then-current whereabouts, and it must be considered possible that Rolfe was working from false or outdated information. Rolfe cannot now recall any details of this initiative (written communication via Jeff Liston, Royal Tyrrell Museum of Palaeontology, 2022) and it is considered unlikely that any further relevant correspondence survives or is discoverable (Michael A. Taylor, University of Bristol, written communication, 2022).

In an unpublished manuscript, Madsen (1990, p. 4) wrote that “The fate of the initial set of molds is somewhat in question, but Wann Langston (written communication, 1989) suggests that they seem to have been lost, strayed, or stolen during transport from ? to ?. Principles [sic] contacted in regard to the disposition of the molds could not provide specific information.” Infuriatingly, the question marks are in the original. Since both Langston and Madsen are now deceased, there is no way to discover on which journey Langston thought the molds were lost or destroyed. It is unlikely, at least, that Langston had in mind their initial journey from Vernal to Rocky Mount. Kirby (1998, p. 4) wrote that “Somewhere along the line, as the story goes, the molds received from the Carnegie had been shipped to a school down south and never arrived. So they were lost.” Since Rocky Mount is about 2000 miles east (not south) of Vernal, it might seem that “a school down south” could not have referred, in a Utah publication, to a museum in the east. On the same basis, the Houston Museum would not seem an especially likely candidate for this designation, being 1300 miles southeast of Vernal. However, “down south” in the USA does not necessarily refer to strict geographic direction, but to “The South,” a region composed mostly of states that

were Confederate during the Civil War, a designation that includes both North Carolina and Texas.

Yet another account of the molds is described by David S. Berman (verbal communication, 2022), relating a verbal communication from John S. McIntosh. In this version, a person who had obtained the molds for the use of a public museum, most likely Harold Minges for the Rocky Mount Children’s Museum, became embroiled in a dispute with the museum administrators and sequestered the molds in a barn. There they remained for some time until the rubber straps that held together the molds constituting each element perished, and the 600 pieces that made up the molds became hopelessly jumbled. Re-associating the pieces would have been an enormous job, as some of the more complex vertebrae were made from 20 to 30 molds (Nieuwland, 2019, p. 63), and it was probably never done. Most likely, the dissociated pieces of the molds would have been discarded sometime later.

Putting it all together, there is no way that all the reports cited here can be accurate. Among the more likely scenarios is that the molds were successfully shipped to Rocky Mount in July 1960 (Anonymous, 1960a, 1960b), but some way into the casting project they were found not to be up to the job (Rea, 2001, p. 210; Moore, 2014, p. 234–235) and left in storage. At some later point it may be that they were shipped to a school in a southern state (Kirby, 1998, p. 4) but did not arrive (Langston cited in Madsen, 1990, p. 4). It is possible that this happened in late 1988 or early 1989, between Rolfe’s (1988) letter that expressed an interest in using the molds and Langston’s personal communication to Madsen in 1989. But since this scenario is assembled from fragments, it is perhaps more parsimonious to assume that McIntosh’s account via Berman is correct. At any rate, where the molds are now, if they survive at all, we can only speculate. As Madsen (1990, p. 4) concluded, “It is truly a mystery that an estimated 3–6 tons of plaster molds could simply vanish!”

The Lightweight Cast in Vernal

By the late 1980s, the concrete *Diplodocus* was inevitably deteriorating (Madsen, 1990, p. 3). Museum staff decided they wanted a new, lightweight cast of *Diplodo-*

cus to mount indoors. As noted above, the 50-foot-long galleries could not accommodate a 76-foot-long mount at its full length, but it was decided to curve the tail to enable it to fit. That of course had been an option in 1957 when the concrete cast was created, but perhaps Untermann, then the museum director, had wanted the tail laid straight out. Untermann had died in 1975, two years after his wife Billie (Lewis, 1977); a decade after his death, his preference would not have held such weight.

On January 26, 1988, Alden H. Hamblin, then Park Superintendent of the Utah Field House, informally discussed with William C. “Lucky” Murdock, director of the Las Vegas Museum of Natural History, the possibility of having the Las Vegas museum make molds from the concrete cast. Murdock’s January 28, 1988, letter of confirmation (Murdock, 1988) proposed a deal where the Las Vegas museum would make a new fiberglass cast for the Field House and mount it for them in Vernal, and would retain the concrete cast as well as the new molds, with permission to cast additional specimens. James E. King, director of the Carnegie Museum of Natural History, got wind of this plan and wrote on February 23, 1988 to Hamblin and Murdock requesting that only two casts (for Las Vegas and the Field House) be made from the new molds (King, 1988).

Negotiations progressed to the point where a draft contract was written up (Las Vegas Museum of Natural History, 1988), with the intention of signing it on March 8, 1988. This version of the agreement was more favorable to the Field House; the Las Vegas Museum was to disassemble and transport the concrete *Diplodocus*, make molds from it, and cast two fiberglass replicas from them. It would retain one and display it with acknowledgment to the Field House; and it would keep the new molds in storage but they would belong to the Field House. The Las Vegas Museum was to return the concrete original and the second fiberglass replica to Vernal, and mount the new Vernal cast in the Field House. All of this was to be done at the Las Vegas Museum’s expense and under its own insurance. The agreement stated that the work would be completed by June 30, 1988, which seemed highly optimistic. Additional casts would be made only with written permission from both the Field House and the Carnegie Museum. These plans were briefly noted by Krishtalka (1988, p. 17).

However, the arrangement with the Las Vegas Museum fell through. In a letter to James H. (Jim) Madsen, Jr., Field House Curator, Sue Ann Bilbey said only that “Las Vegas is no longer interested in obtaining a copy or making new molds” (Bilbey, 1989), and a letter from Royal Museum of Scotland’s Keeper of Geology William D.I. Rolfe (1988) to LuRae Caldwell of the Field House makes it clear that the Las Vegas plans had been abandoned by October 24, 1988. The Las Vegas Museum was to go bankrupt and close in 1990 (Michele Jones, Las Vegas Natural History Museum, written communication, 2022), so it seems likely that its waning interest was due to lack of funds.

With the Las Vegas plans having failed, and with little funding of its own, the Field House was in a difficult position. The plan at this stage was to move the existing concrete cast indoors (Bilbey, 1989). Bilbey again wrote on April 2, 1989 to James H. Madsen of Dinolab, Inc., floating the possibility of a collaboration along the broad lines of those of the failed Las Vegas deal, but leaving it to Madsen to propose the details in a way that would make the project commercially worthwhile for Dinolab (Bilbey, 1989). At this time, the Royal Museum of Scotland was very interested in obtaining a complete skeleton (Bilbey, 1989). Madsen replied on May 16, 1989 with some caution (Madsen, 1989a), proposing that Dinolab might make the project financially viable by creating up to 15 additional *Diplodocus* copies from molds that it would make from the Field House’s concrete cast, but expressing concern about the size of the project and worrying that “details and approvals may become too tedious to work with,” most likely a reference to the Carnegie Museum’s reluctance to allow multiple copies to be made (King, 1988). It does not seem that the Carnegie Museum had any actual authority to veto the creation of new casts, but all parties would have been reluctant to alienate an important ally.

Madsen’s reservations were evidently overcome, the project was quickly begun, and by the time he wrote to Hamblin on June 12 (Madsen, 1989b), he was able to say “We are into the work with gusto.” It became apparent that a great deal of work was necessary to clean, stabilize, and repair the concrete casts, which had suffered badly from three decades of climate extremes, before they could be used to make new molds (Madsen,

1989b). A year later, Madsen (1990, p. 3) would write that “It is evident now that the decision at that time to dismantle and repair the skeleton was a wise one, since close examination during preparation and stabilization has revealed incipient fracturing and surface deterioration due to weathering of numerous elements [...] Such damage would have been progressively more difficult, if not impossible, to repair after a few more years of precipitation and the temperature extremes typical of the harsh winters and hot summers of the Uintah Basin.”

The arrangement with Dinolab was formalized by a contract dated June 30, 1989 (Madsen and others, 1989), although work had already begun before this was signed. The work was eventually to take more than two full years. During this time, Dinolab repaired the deteriorated concrete cast as detailed above, restoring and sealing the bones. They then made new molds from the repaired concrete *Diplodocus* elements, and used these new molds to create a new lightweight indoor *Diplodocus* for the Field House, largely using WEP. As Madsen’s (1990, p. 1) unpublished manuscript explained, they “used a variety of plastics in different combinations for casting individual bones [...] For example the elements of the axial skeleton, manus, pes, and skull are cast in W.E.P. (water extended polyester); while the ribs, ilia, femora, humeri, and scapulae/coracoids are all hollow cast in a gelcoat with fiberglass and resin. Other newly developed hollow-cast techniques may be used as well. A tinted gelcoat (resin) is used as a base in producing the fiberglass elements to simulate the natural color of the original, fossil bone. The W.E.P. parts may also be tinted to approximate the color of the original bone.”

Dinolab intended to improve the Field House cast beyond merely duplicating its concrete predecessor: “alterations were also made to improve the scientific accuracy and integrity of the specimen. For example the manus and pes were earmarked for replacement with elements (or casts) provided by (?) [sic], when it was confirmed that those in the original mount were camarasaurid rather than diplodocid (McIntosh, 1981)” (Madsen, 1990, p. 3–4). The question mark is unfortunately in the original. Madsen is in error here, as McIntosh (1981) says that the right pes of the Carnegie mount is taken from CM 94, a referred specimen of *Diplodocus carnegii*, but does not say where the left

pes was taken from. The replacement of the forefeet by diplodocid material would definitely be an upgrade. However, it seems that this was not done: the present Field House cast has the same old-style forefeet as the original Carnegie mount had, with unguals on all of the first three digits. By contrast, the cast in the Museum für Naturkunde Berlin has revised forefeet with fewer phalanges and unguals only on digit I (Taylor, personal observation). It may be that the Berlin mount still uses the originally supplied camarasaurid pes casts, but has re-posed them and discarded the excess phalanges and unguals.

Using the new molds, which they retained, Dinolab reserved the right to make up to 20 additional casts, with the Field House to receive \$5000 for each one sold (Madsen and others, 1989). This was a significant concession from the Carnegie Museum, which had previously wanted to limit the number of new casts to two. Perhaps it was made possible by a clause saying that “if the Carnegie identifies and refers to Dinolab a new buyer who ultimately purchases a new replica, Dinolab will pay to the Carnegie a commission of \$3,500.” Hamblin obtained from Jerry Miller (the Director of Utah Division of Parks and Recreation) a formal statement that royalties obtained from additional casts would be used for exhibits at the Field House (Hamblin, 1990).

Dinolab was contracted to deliver the indoor mount to the Field House not later than June 30, 1991, and it arrived only a few days before this (Anonymous, 1991). The concrete skeleton had been returned to the Field House, too, but it “remain[ed] in a back room in the fieldhouse. It [could] not be reassembled because when it was taken apart linking material had to be cut” (Anonymous, 1991).

The Dinolab contract was in one respect inferior to that agreed with the Las Vegas Museum. In the older agreement, Las Vegas would have been responsible for mounting the Field House’s new cast, but Dinolab undertook only to provide “technical assistance [...] in the design, fabrication and construction of a free-standing exhibit incorporating that skeleton” (Madsen and others, 1989). It was intended that the new cast would be assembled that winter (Anonymous, 1991), but delays were to prevent the public from seeing it for nearly three further years. By June 23, 1993, only the limbs and tor-

so had been erected (Anonymous, 1993). In June 1994, the mount of the new cast was finally completed, with its head and neck looming over the admission counter (figure 8). It was unveiled as part of the Dinosaur Days festival on Saturday, June 18 (Morrison, 1994), having been “pieced together by maintenance employee, Danny Anderson, who worked on him over a two year period only as time allowed.” Anderson had been working at the museum on and off since 1988, and since 1991 had been full time. One of the questions he had been asked when interviewing for the job in mid-October 1991 was whether he could assemble the *Diplodocus* (Kirby, 1998, p. 3). Evidently, he had the necessary skills and ingenuity, but other responsibilities meant that very nearly five years were to elapse after the removal of the outdoor concrete *Diplodocus* before the unveiling of its

indoor WEP successor.

The lightweight *Diplodocus* that dominated the original Field House exhibit hall was in place for only ten years before the museum moved to a new and much larger purpose-built facility on May 22, 2004. The WEP cast was taken down and remounted in a more dynamic pose in the entry hall of the new museum, where it remains to this day (figure 9).

New Casts Made From Molds of the Concrete *Diplodocus*

In subsequent years, further casts were made from the Dinolab molds. Table 1 summarizes information from Madsen’s (1993) report to the Carnegie Museum and the Field House, together with additional in-

Figure 8. The second-generation lightweight *Diplodocus* cast as originally displayed at the old Field House building between 1994 and 2004. (A) Right anterolateral view, showing the head and neck projecting above the admission counter. (B) Left posterolateral view, emphasizing the curvature of the elevated tail necessary to fit the 76-foot-long skeleton into the 50-foot-long exhibit hall. Photographs taken in May 1999 by Chet Gottfried, using a Pentax LX camera with a 17 mm rectilinear fisheye lens. Used by kind permission.

Table 1. Casts made from the molds taken from the concrete *Diplodocus* of Vernal. This table represents a synthesis of three sources of information: (1) a list maintained by Dinolab and forwarded by Brian D. Curtice, (2) James H. Madsen’s (1993) memorandum to Mary Dawson (Carnegie Museum) and Alden H. Hamlin (Utah Field House), and (3) an accounting made by Dinolab to Steve Sroka shortly after he started work at the Field House (Dinolab, 2001). The first of these sources lists specific cities that the casts were sent to, includes dates, and extends to #13. The second source only applies to the first four casts, which lists clients, gives regions rather than cites, and notes what royalties were paid. The third source notes where payments were made “in kind” as contribution towards the cost of a *Stegosaurus* cast. Note that Dinolab’s numbering of the casts does not proceed in chronological order, and that casts 9–12 are not recorded in the available documents. N/A = Not Available.

formation from Dinolab, kindly provided by Lisa and Chris Madsen. Of particular interest is that Dinolab are claimed to have supplied a cast to Odawara in the Kanagawa prefecture of Japan in January 1990 before delivering to the Field House. This must be considered doubtful, as the work, begun with the collection of the concrete cast only in June 1989, could scarcely have progressed far enough to deliver a complete cast only seven months later; a date of January 1992 (nine months after the Vernal delivery) is more likely.

Some reported subsequent casts have proven difficult to track down. For example, Nieuwland (2010, p. 68) reported that the new molds “opened up the possibility of a whole slew of further copies of this particular copy, which was immediately exploited by the Las Vegas Natural History Museum. One of these has been placed in the Las Vegas Natural History Museum.” But this seems to be an error based on misunderstanding Krishtalka’s (1988, p. 17) report of an earlier Las Vegas museum’s intention to make its own molds of the concrete *Diplodocus* as discussed above. The Las Vegas

Museum of Natural History (note the subtly different name) went bankrupt and closed in 1990, before the new molds were available for casting, so it could not have received a *Diplodocus* cast. The Las Vegas Natural History Museum, a completely different institution, which opened in June 1991, has never had a *Diplodocus* (Michele Jones, Las Vegas Natural History Museum, written communication, 2022).

The molds taken from the concrete *Diplodocus* were used again in an eighteen-month project in 1996 and 1997, led by David Letasi, to create a unique exhibit at the Museum of Science and Industry (MOSI) in Tampa, Florida (David Letasi, formerly of MOSI, written communication, 2022). When Susan Swartz of MOSI obtained a \$500,000 grant from the National Science Foundation for its “Assemble a Sauropod” project, the museum board were initially interested in purchasing a cast of a large sauropod skeleton from China. However, based on photographs of this skeleton, Letasi was skeptical about its authenticity. On advice from Mark Norell (American Museum of Natural History), Letasi con-

Figure 9. The second-generation lightweight *Diplodocus* cast as currently displayed at the new Field House building since 2006. Skeleton in right lateral view, with *Homo sapiens* Michael P. Taylor for scale. Photograph by Mathew J. Wedel.

sulted Paul Sereno (University of Chicago), who had recently seen the specimen in question, and discovered that it was almost entirely extrapolated from a handful of bones; these were so restored with plaster that it was impossible to determine what was real. Sereno therefore wrote to the museum directors, recommending that the project take a different form. Jim Kirkland (State Paleontologist with the Utah Geological Survey) who was lecturing at a MOSI event at this time, recommended that a *Diplodocus* skeleton could be used, and that Jim Madsen was able to produce the casts, using the molds taken from the concrete *Diplodocus* of Vernal.

The museum directors approached Madsen, who recommended that two individuals of *Diplodocus* be

created and posed together, creating a unique tableau. Letasi conceived the idea of mounting one of them in a rearing position. To better understand what this would entail, he consulted Mark Norrell, who six years earlier had mounted a cast of *Barosaurus* skeleton in the American Museum of Natural History atrium (Taylor and others, in preparation b). Letasi also consulted Robert Bakker on the active, defensive pose of the quadrupedal skeleton; Phil Currie on the dynamics of the whiplash tail; and Kent Stevens on the mechanics of the rearing posture. Sauropod specialist John S. McIntosh reviewed the resulting design.

The elements of the mounts were cast by Jim Madsen of Dinolab, using hollow core resin casting with

lightweight foam filler to reduce weight. Whereas the postcranial skeleton was created from the second-generation Vernal molds, the cast skull was based on a separate Carnegie Museum individual, CM 11161. All these elements were then shipped to Ontario to be assembled into their selected postures by Peter May of Research Casting International (RCI) with guidance from Letasi.

Aside from biological and mechanical verisimilitude, it was also necessary to consider the space the skeletons were to be mounted in. Letasi was concerned that it would be difficult to place the mounts in the main lobby without restricting evening events, as the space was used for public dinner engagements and rotating exhibits. With space in the lobby limited, it was not clear that the skeletons, widely cited in the literature as being 85 feet in length, would fit. At Letasi's request, Jim Madsen laid out the skull and axial skeleton at his lab, and measured it at 75 feet, so it appears that the 84 feet given by Holland (1905, p. 448) for the London cast was an exaggeration.

Letasi visited RCI for the trial mountings of both skeletons. The only problem that became apparent was the position of the tail on the upright mount, which when installed at the museum would have collided with a balcony. The tail posture was changed and the problem avoided. The two mounted skeletons at their true size of 75 feet, and with the tail posture modified, were able to fit perfectly into the MOSI lobby. The upright mount was placed on a 10-foot-high pedestal and an existing concrete bunker was used for the quadrupedal mount, so neither encroached greatly on floor space (figure 10).

Sadly, this impressive exhibit was to last only 20 years in its original form. On August 13, 2017, the museum, in financial difficulties, closed 85% of its space (Contorno, 2017; Schreiner and Ochoa, 2017) and many exhibits had to be discarded. Happily, in 2019 the rearing mounted *Diplodocus* was moved to a new position in the Kids In Charge Gallery in the surviving part of the museum. The quadrupedal mount was sold to a company that in turn sold it on to RCI who had mounted it in the first place. At present, this cast is on display at the Cleveland Museum of Natural History in Cleveland, Ohio, as a filler while RCI mounts their *Haplocanthosaurus* skeleton, and its intended destination after that is the Quinte Natural History Museum,

Trenton, Ontario (Peter May, Research Casting International, written communication, 2022), only 100 yards or so from RCI's workshop.

In addition to providing complete casts of *Diplodocus carnegii*, Dinolab negotiated the right to use the Vernal molds to create individual elements for various museums (Madsen and others, 1989, p. 1). In 1989 or 1990, sauropod expert John S. McIntosh helped to broker a deal between Dinolab and RCI whereby Dinolab created casts of the *Diplodocus* elements needed to make up the missing parts of the AMNH *Barosaurus* mount. This was necessary as the material of other known *Barosaurus* specimens would not have filled the gaps, and *Diplodocus* was at that time the most closely related known sauropod to *Barosaurus*. See Gordy (1991), Norell and others (1991), Dingus (1996, p. 20–29), and Taylor and others (in preparation b).

The Fate of the Concrete *Diplodocus*

The contract that the Utah Field House negotiated with Dinolab (Madsen and others, 1989) stipulated that the 1957 concrete cast, having been repaired, would be returned to the Field House. But when the cast was returned to them some time before the end of June 1991, it was not a simple matter to remount it outside the museum, as the scaffolding on which the cast was mounted had been cut in order to take it down (Anonymous, 1991). As a result, the concrete cast was never remounted at the Field House, and was instead stored in the building crawl space. The femora, separated from the rest of the skeleton, were left outside the building in a children's sandbox "dino dig" area.

As noted above, the Field House Museum moved to a new purpose-built building on May 22, 2004, and the WEP cast was remounted in the entry hall. The concrete cast was left behind in the old building. In 2012, however, all Field House materials had to be removed from the old building, as Uintah County had traded the old building for the new, and the agreement for the Museum to continue using the old building had expired. A company was hired to demolish what remained, including built-in exhibit cases, the front counter, etc. One of the demolition company workers, assuming the femora were abandoned, took them home. Ken Carpenter sug-

Figure 10. Double *Diplodocus* mount at the Museum of Science and Industry (MOSI), Tampa, Florida. Both individuals are identical, having been cast from the molds made by Dinolab from the concrete *Diplodocus* of Vernal. Photograph by Anthony Pelaez, taken between 1997 and 2017.

gested posting a news article requesting the return of the bones, and the workman came forward with them enabling the femora to be reunited with the rest of the concrete skeleton.

At this time, the concrete casts were squeezed into collections at the new building, but there was not room for them to be properly stored and they had to sit in the middle of the repository aisle. It was apparent that, despite the concrete cast's important role in the Field House's history, it was no longer wanted.

Since the cast was state property, it had to go to a state repository. Steve Sroka, the museum paleontologist, therefore contacted Ken Carpenter to ask whether Utah State University (USU) could take it. On April 29, 2013, Utah Division of Parks and Recreation signed a memorandum of understanding with the USU Eastern Prehistoric Museum in Price (Carpenter and Hayes, 2013), agreeing that the concrete cast would go on an

effectively permanent loan (99 years, renewable) to the Prehistoric Museum. The cast was collected on April 8, 2013 (figure 11A). It then sat in Carpenter's garage for a year (figure 11B), until Carrie Herbel, a preparator at the Prehistoric Museum, obtained a \$5000 grant from the Utah Museums Association for the repair of the casts.

Given that the casts had been in storage since Dinolab's 1989–1990 repairs, when they undertook to “stabilize, restore and seal the concrete casts of the individual bones,” it is surprising that the Prehistoric Museum found every bone to be damaged. It took Herbel nine months to sandblast the old paint off (figure 12) and repair the broken and missing pieces using a concrete patch used to repair airport runways.

It was never an option to mount the repaired concrete *Diplodocus* outside the Prehistoric Museum's current building; there is no space on the south side be-

Figure 11. The elements of the concrete cast moving from Vernal to Price, Utah, on April 8, 2013. (A) The concrete cast packed onto wooden pallets outside the new Field House building, having been prepared for transportation to the Utah State University Eastern campus in Price, about 100 miles southwest of Vernal. Photograph by Steven D. Sroka. (B) The same bones having been unpacked into Ken Carpenter's garage in Price, Utah. Photograph by Ken Carpenter.

cause that is where the city holds outdoor events, and no room on the north side because of the parking lot and overhead main power line for downtown businesses. The intention was that the cast would be mounted outside a new museum in Price, which was then in the planning and fund-raising stage. However, due to funding difficulties this museum was never built and the land that had been donated for the museum was returned to the donor. In light of these developments, Carpenter discussed with the USU chancellor the possibility of temporarily mounting the skeleton on campus. However, this idea was not implemented since Carpenter feared that mounting and later dismantling the cast to move it to a new museum would damage it. Therefore,

it currently sits in the basement storage area on the USU Eastern campus (figure 13), waiting for a new museum to be built where it can be displayed outdoors.

The Fate of the New Molds

Dinolab began to wind down after its proprietor Jim Madsen died in 2009 aged 77 (Anonymous, 2007). In 2019, Dinolab's storage building in Ogden, Utah, was scheduled for demolition, so new homes had to be found for the stored materials. The *Diplodocus* molds that had been taken from the concrete cast were moved to Research Casting International (RCI) in Trenton, Ontario, Canada. Here, they were kept in storage for

Figure 12. Carrie Herbel, a preparator at the Prehistoric Museum in Price, sandblasting old paint off the concrete *Diplodocus* casts recently obtained from Vernal, on November 1, 2014. By comparison with Hatcher (1901, plate V), which shows anterior-view photographs of the cervical vertebrae of *Diplodocus carnegii* holotype CM 84, this appears to be the cast of the 15th and last cervical, based on the wide zygapophyseal facets, the broad diapophyseal wings, the well-developed “V”-shaped intraprezygopophyseal lamina, and the tall, well-separated halves of the bifid neural spine with little dorsal expansion.

Dinolab; some of them still in good condition, some in rough shape. At the time of writing, these are probably the only Carnegie *Diplodocus* molds in the world.

DISCUSSION

Projects like the casting and mounting of the concrete *Diplodocus*, the subsequent remolding from the elements of the mount, and the creation of the second-generation WEP cast are historically and scientifically significant, and it is important to document how and when they were done. We are fortunate in the present case to have Untermann’s (1959) account of the initial casting in concrete as a basis; but subsequent to that point, as with so many dinosaur-mounting exercises, documentation has been lacking. It has been a lengthy and painstaking process to reconstruct the history, more than six decades after some of the events, largely by reference to contemporary newspaper reports, unpublished letters and memos, and personal recollections—many of them second hand. Even with our best efforts, though, frustrating gaps remain, not least the mysterious ultimate fate of the original Carnegie *Diplodocus* molds. We urge museums undertaking large-scale projects to ensure that they are formally documented as they are taking place, and to publish an account of their work, as for example the Museum für

Naturkunde Berlin did with the 2007 remounting of *Giraffatitan* (Remes and others, 2011).

Working on this project has been a rather melancholy task at times. It is noticeable that projects which begin with excitement often end rather forlornly, or trail away into nothing. The original Carnegie molds yielded the *Diplodocus* replicas that were received with such excitement in London, Paris, and other great cities. However, they were lost, stolen, or destroyed sometime between 1960 and 1990; more than that, we cannot say. The replica *Diplodocus* that was to have been erected in Sunset Park by the Rocky Mount Children’s Museum was either destroyed by Hurricane Floyd, or more likely never made at all. The concrete *Diplodocus* that was such a celebrity in Vernal for three decades, which was supposed to have been repaired by Dinolab and returned to Vernal for remounting was never re-erected, but shipped to a garage, thence to another museum’s basement, where it awaits the building of yet a third museum. The new molds that were made from the concrete casts seem to have sat unloved in the Dinolab building for some years until it was torn down, and now they lurk in RCI’s storage. The double *Diplodocus* display at MOSI was taken down as part of a retrenchment program to save the museum money, and one of the skeletons sold back to the company that had mounted it.

Figure 13. The elements of the concrete cast as they are now, having been cleaned and stored in the basement storage area on the Utah State University Eastern campus in Price, Utah. Photograph by Jason Huntzinger (Utah State University).

Even the *Diplodocus* that started it all, the cast presented by Andrew Carnegie to the British Museum (Natural History) on May 12, 1905, seems to be ambling towards an undistinguished fate. Having been the centerpiece of the museum’s main hall for nearly four decades, it was removed in 2017 to make more space for corporate events (Steerpike, 2015; Nieuwland, 2019, p. 260). The cast was sent on a tour of the UK, but now that this has concluded, “in all likelihood the plaster dinosaur will meet an inglorious end in the basement of the museum” (Nieuwland, 2019, p. 4). However, while

the fate of the London cast stands as a stern warning of what can happen when commercial considerations supersede a museum’s actual mission, there remains hope for the concrete *Diplodocus* of Vernal, which may yet become the concrete *Diplodocus* of Price.

ACKNOWLEDGMENTS

No paper is ever written without the help of other people, and that is especially true of this one. In tracing the multiple intertwining strands of history that make up this story, we have been helped repeatedly by people

going far beyond the call of duty to dig out old information for us. In the isolating times in which we live, with political polarization and the ongoing Covid pandemic, it is deeply gratifying to feel part of a global network of people working generously together. We thank the following people, with apologies to anyone we have overlooked.

Elaine Carr (Uintah County Regional History Center) furnished high-resolution images from the History Center archives and helped us to trace the history associated with some of them. Leigh White (Rocky Mount Children's Museum) provided invaluable information about the museum. Michele Jones (Las Vegas Natural History Museum) explained to us the various natural history museums that have existed in Las Vegas. David Letasi (formerly of the Museum of Science and Industry, Tampa, Florida) provided extensive background on the double *Diplodocus* mount at MOSI. Chris Madsen (Dinolab, Inc.) identified his father's unpublished manuscript (Madsen, 1990); he and his sister Lisa Madsen (Dinolab, Inc.) gave permission to list Dinolab's records of *Diplodocus* casts created from the Vernal molds. Josh Lively (Prehistoric Museum, Price, Utah) helped us to recover old photographs taken by Ken Carpenter. Chet Gottfried provided photographs of the Field House's WEP cast, in its original location, for figure 8. Mathew J. Wedel provided the photograph of the Field House's current *Diplodocus* mount for figure 9. Anthony Pelaez (Museum of Science & Industry, Tampa, Florida) provided the photograph of the double *Diplodocus* mount for figure 10. Jason Huntzinger (Utah State University) supplied the photograph of the concrete elements in collections for figure 13. Andy Farke (Raymond M. Alf Museum of Paleontology) and John Foster (Utah Field House of Natural History) went to great lengths attempting to help us track down references. Traci Thompson (Braswell Memorial Library) helped us to track down newspaper articles on the Rocky Mount *Diplodocus* project. Robert Bakker (Houston Museum of Natural Science), Brian Curtice (Fossil Crates), Jeff Liston (Royal Tyrrell Museum of Palaeontology), Peter May (Research Casting International), Ilja Nieuwland (Huygens Institute, Royal Netherlands Academy of Arts and Sciences), and Michael A. Taylor (National Museums Scotland) allowed us to cite written communica-

tions. David S. Berman (late of the Carnegie Museum) provided verbal communication.

Online digital archives were invaluable in preparing this paper. Among those we used are the following. (1) The J. Willard Marriott Digital Library of the University of Utah at <https://collections.lib.utah.edu/> provided many photographs of the concrete *Diplodocus*, and the metadata associated with the photographs contained information that was useful to us. (2) Utah Digital Newspapers at <https://newspapers.lib.utah.edu/> search contained exhaustive archives of the *Vernal Express*, which were crucial in reconstructing the story. (3) Newspapers Archive at <https://newspaperarchive.com/> included coverage of the Rocky Mount *Evening Telegram*.

Many of the letters and newspaper articles referenced herein can be found in the archive at <https://github.com/MikeTaylor/palaeo-concrete>.

We are grateful to Doug Sprinkel (Azteca Geosolutions) for his efficient editorial handling of this paper, and to Brian D. Curtice (Fossil Crates), and Paul D. Brinkman (North Carolina Museum of Natural Sciences) for detailed, careful, and constructive reviews.

Our dearest hope for this paper is that it inspires someone to create a Dungeons and Dragons module in which the Concrete *Diplodocus* of Vernal is a quest artifact with magical powers.
